

Measured steering · 5 September 2026

GPT-OSS-20B · historical permission task · case 001 · seed 71

Saved September 5 measurements; these are not interventions on the September 11 gardening inputs.

All points are Tool-output tokens (purple): 59 matched tokens per panel, first prefill only, with raw probabilities.

The mean Tool – User direction is added at block 11 output; a separate local five-role probe reads block 14.

The signed strengths scale a unit direction by ± 0.3 times the reference residual norm. Only command spans are directly steered.

Observed writes: A permitted $\rightarrow$ baseline A, both steering signs A+B. B permitted $\rightarrow$ A+B under all three conditions.

The scores change sharply while selective execution can still fail. This figure uses saved data; no new model inference.
